Handover Note

TrustLens — FYP Documentation Package For: Haseeb Ur Rehman (2022F-mulbsswe-043) and Muhammad Muttayab (2022F-mulbsswe-012) Prepared by: Zohaib Khan (contracted developer) · 2026-08-31

This package documents TrustLens as it actually exists today, for your 8th-semester FYP submission to Mam Misbha and the FYP evaluation committee at the School of Software Engineering, Minhaj University Lahore. Read this note first — it's the only file in the package meant to be read in full in one sitting; everything else you'll dip into as needed.

What's inside

File / folder	What it's for
`01-Simple-Guide.md`	Plain-language explanation of the whole project, plus 15 likely viva questions with honest answers. **Read this together before your viva**, even if you skip everything else
`02-Index.md`	This folder's own table of contents, reading paths, and the screenshot gallery
`03-SRS.md`	Software Requirements Specification (IEEE 830) — what the system must do
`04-SDD.md`	Software Design Document (IEEE 1016) — how it's built, with 20+ diagrams
`05-Test-Cases.md`	Test Documentation (IEEE 829) — what was actually tested vs. only planned, and the real defect log
`06-User-Manual.md`	How to use the finished product, with real screenshots
`07-Thesis.md`	The full thesis manuscript — front matter, 8 chapters, references, appendices
`screenshots/`	The real captured screenshots used throughout the package
`diagrams/`	Rendered PNG versions of every Mermaid diagram (used inside the Word thesis)
`pdf/`	Page-numbered PDF edition of every document above, for reading and printing
`Project_Thesis.docx`	**The actual submission copy** — a bound Word document (A4, Times New Roman, binding margin, roman-then-arabic pagination)

Do these things before you submit

1. **Open `Project_Thesis.docx` in Word, click into the Table of Contents, and press F9 → "Update entire table."** No script can compute real page numbers — that only happens inside Word, once, by you.

2. **Read `05-Test-Cases.md`'s banner at the very top before you write or say anything about testing in your report or viva.** It states plainly how many test cases were actually executed vs. only specified. Do not round that number up.
3. **Sign the certificate-of-approval and declaration pages** in the thesis front matter — they have real signature-line blocks, left blank intentionally.
4. **Check your institution's exact required wording** on the certificate/declaration pages against what's here — this was written from the standard FYP submission form, not a copy of a signed institutional template.
5. **Read `05-Test-Cases.md` §6, the defect log, in full.** Two of the fifteen logged defects are still open (MFA is unimplemented; the admin panel is incomplete) — know these before a panel member finds them for you.
6. **Rehearse `01-Simple-Guide.md` §9's viva questions out loud**, especially the ones about the scam classifier's real accuracy and the fact that nothing is deployed publicly yet. Panels ask the uncomfortable question; a fluent honest answer defends better than a confident evasive one.

Do NOT do these things

- **Do not hand-edit any generated file** (`docs/pdf/*.pdf` , `docs/diagrams/*.png`) — they're regenerated from the Markdown sources. Edit the `.md` file and rebuild.
- **Do not submit the browser-print PDF of the thesis.** `pdf/07-Thesis.pdf` is a reading/email convenience copy. The actual submission copy is `Project_Thesis.docx`, exported to PDF from Word *after* you've updated the Table of Contents.
- **Do not present "51 test cases specified" as "51 test cases passed."** They are different numbers, stated separately on purpose in `05-Test-Cases.md` .
- **Do not claim the system is deployed publicly.** It is not, as of this document. Say so plainly if asked — the deployment plan is designed and partly rehearsed, not live.
- **Do not claim validated real-world OCR/face-match accuracy.** No consented real CNIC/selfie test set has been collected yet — that's still an open item, and it's yours to close (see below).

Honest status, without spin

The software is genuinely built and working end-to-end for the core journey: a seller can register, verify email, sign in, complete identity/phone/email/device checks, see an explainable Trust Score with a full breakdown, appeal it, have a reviewer decide, and see it recompute. A buyer can look up that score with no account. The engineering is solid — 330 automated tests pass, static analysis is clean, and the codebase follows a deliberately layered, testable architecture. Two real gaps remain open and are documented plainly rather than hidden: the admin panel is functionally incomplete (only the review queue and scoring-

model tuning work end-to-end), and MFA for staff accounts is designed but not implemented. We have **not** independently validated OCR/face-match accuracy against real documents, and the custom scam classifier is measurably weak on real target-domain text (1 of 7 real scam ads caught in a manual check) — which is exactly why it is not yet wired into live scoring. None of this was hidden while writing this package; all of it is written up in `05-Test-Cases.md` and the SDD's honest-limitations sections, because a report that states its real gaps plainly is more credible to a supervisor than one that doesn't have any.

One more thing found live while building this package, worth knowing before your viva: simply signing in and browsing between the three demo seller accounts silently overwrites their intended LOW/MEDIUM/HIGH score spread with a uniform capped HIGH score, because a routine device-fingerprint check triggers a real score recomputation and the demo seed never stored a selfie file for any of them. It's logged as DEF-14 in `05-Test-Cases.md` §6 and is not yet fixed — **rehearse your demo account switching carefully**, or you may find all three sellers showing the same score live in front of the panel. The scores were restored for this package's own screenshots; they will corrupt again the next time someone clicks through all three accounts unless DEF-14 is actually fixed.

What's still yours to do, per `REMAINING.md` Track D in the project root: collect the real CNIC and face test images (this is explicitly a student task, not an engineering one — see `REMAINING.md` Stage 1), rehearse the architecture walkthrough and viva defence, and write and present the final deck. This documentation package supplies the technical content, diagrams, and measured numbers for your report; you write and defend it, because you're the ones at the viva.
